

### NERVOUS SYSTEMS

## Neuron = Nerve Cell

# SIMPLE REFLEX

■ Spinal Nerve

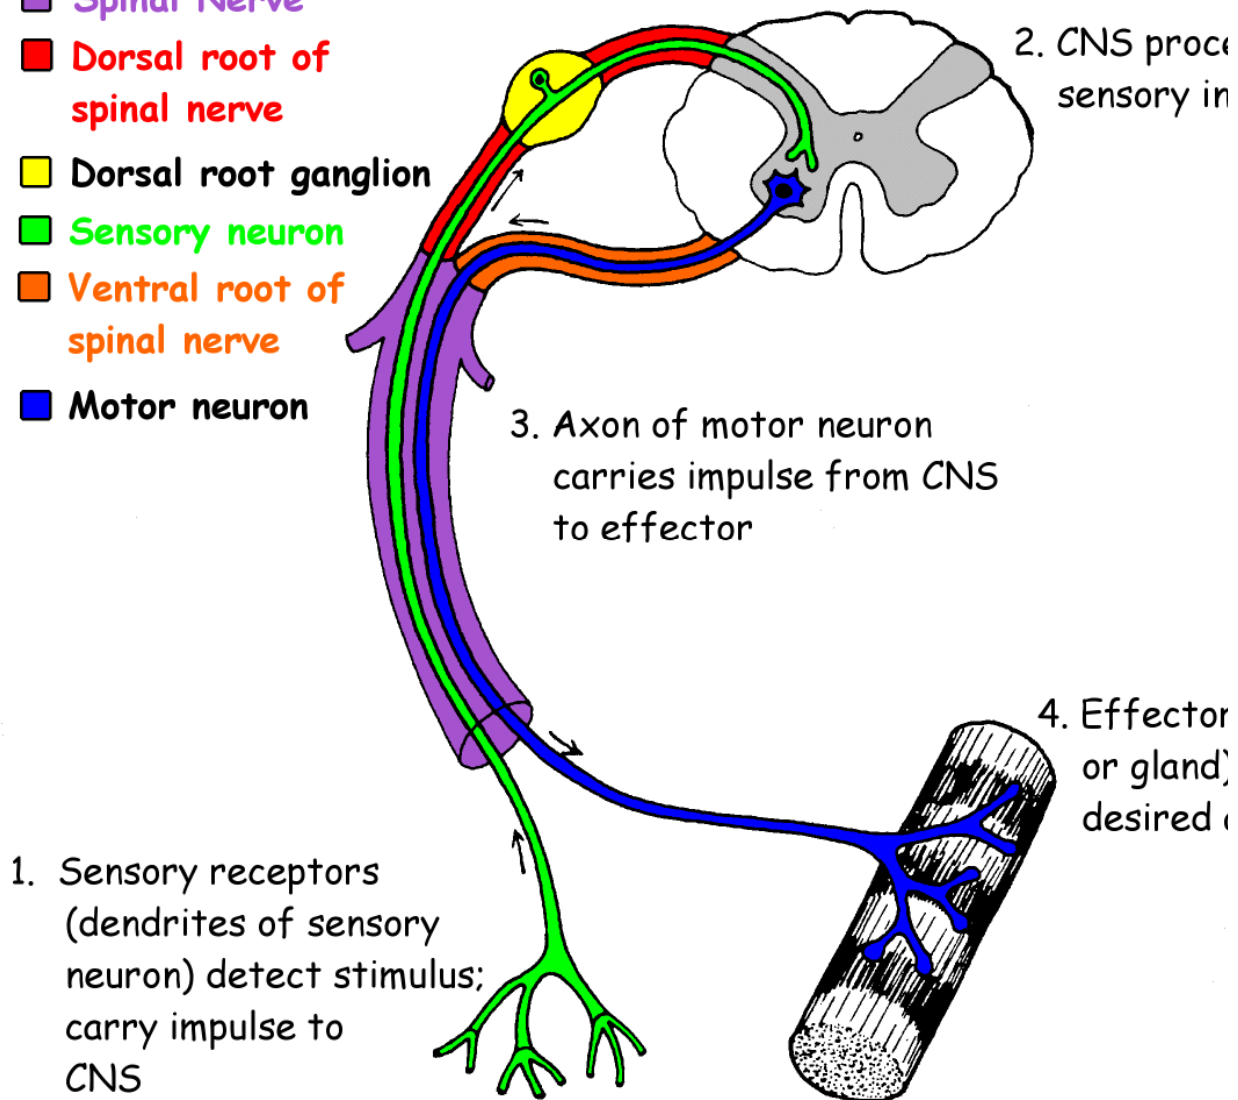

■ Dorsal root of spinal nerve

■ Dorsal root ganglion

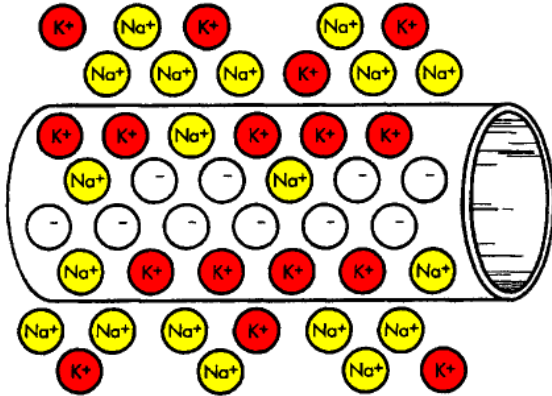

■ Sensory neuron

■ Ventral root of spinal nerve

■ Motor neuron

## RESTING POTENTIAL

- Membrane polarized
- Inside cell more negative than outside
- Difference in charge caused by:
  - Large, negatively charged proteins & nucleic acids inside cell
  - Na<sup>+</sup>/K<sup>+</sup> pumps maintaining excess Na<sup>+</sup> outside cell and excess K<sup>+</sup> inside cell

## ACTION POTENTIAL = Wave of depolarization

1.

2.

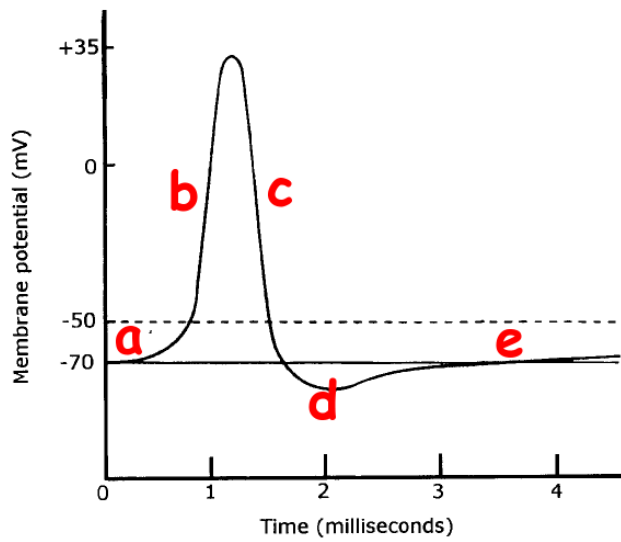

3.

1. Stimulus causes Na<sup>+</sup> to enter cell (depolarization)
2. Depolarization in one area causes depolarization in adjacent area
3. Depolarization continues along length of cell

## ACTION POTENTIAL – GRAPH

### a. Resting potential

-70 mV

### b. Depolarization

- Na<sup>+</sup> ion channels (gates) open
- Na<sup>+</sup> rush into cell
- Membrane potential changes from -70mV to +35 mV

### c. Repolarization

- Na<sup>+</sup> gates close & K<sup>+</sup> gates open
- K<sup>+</sup> rush out of cell
- High K<sup>+</sup> outside cell & high Na<sup>+</sup> inside cell

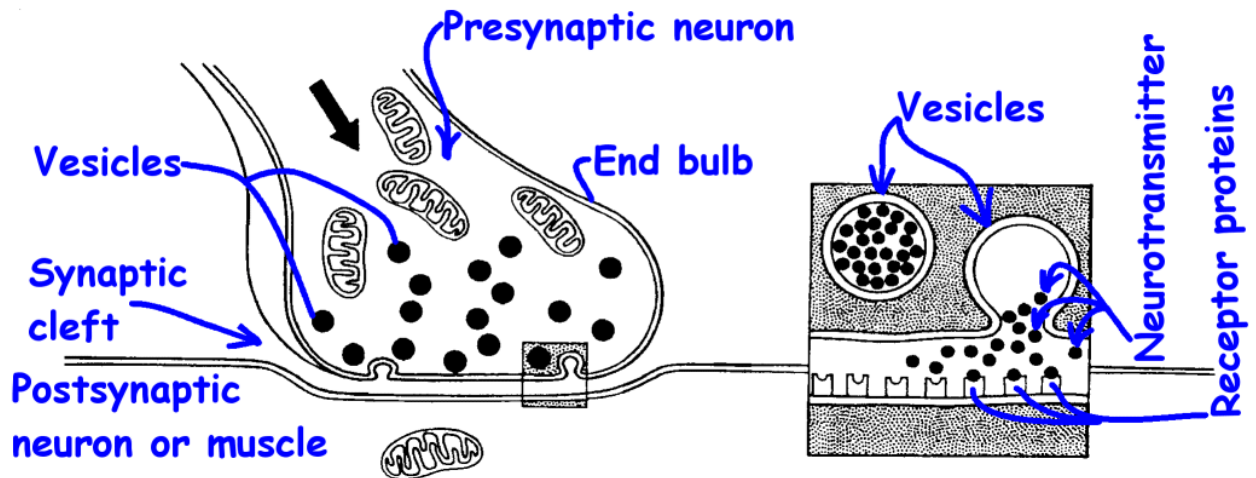

### d. Hyperpolarization

- More K<sup>+</sup> moved out than was necessary
- Neuron cannot be stimulated

### e. Refractory period

- Na<sup>+</sup>/K<sup>+</sup> pumps move Na<sup>+</sup> out of cell and K<sup>+</sup> into cell
- Reestablish original distribution of ions

## TRANSMISSION ACROSS A SYNAPSE

### What happens?

1. Impulse reaches end bulb
2. Presynaptic membrane depolarizes
3.  $\text{Ca}^{2+}$  channels/gates open
4.  $\text{Ca}^{2+}$  enter end bulb
5. Vesicles migrate to presynaptic membrane
6. Vesicles fuse with membrane
7. Neurotransmitter released into cleft
8. Neurotransmitter binds to receptor proteins
9. Postsynaptic neuron depolarizes
